

Problem Set 2

Zahra Khan

Due: February 18, 2026

Instructions

- Please show your work! You may lose points by simply writing in the answer. If the problem requires you to execute commands in **R**, please include the code you used to get your answers. Please also include the **.R** file that contains your code. If you are not sure if work needs to be shown for a particular problem, please ask.
- Your homework should be submitted electronically on GitHub in **.pdf** form.
- This problem set is due before 23:59 on Wednesday February 18, 2026. No late assignments will be accepted.

We're interested in what types of international environmental agreements or policies people support (Bechtel and Scheve 2013). So, we asked 8,500 individuals whether they support a given policy, and for each participant, we vary the (1) number of countries that participate in the international agreement and (2) sanctions for not following the agreement.

Load in the data labeled **climateSupport.RData** on GitHub, which contains an observational study of 8,500 observations.

- Response variable:
 - **choice**: 1 if the individual agreed with the policy; 0 if the individual did not support the policy
- Explanatory variables:
 - **countries**: Number of participating countries [20 of 192; 80 of 192; 160 of 192]
 - **sanctions**: Sanctions for missing emission reduction targets [None, 5%, 15%, and 20% of the monthly household costs given 2% GDP growth]

Please answer the following questions:

1. Remember, we are interested in predicting the likelihood of an individual supporting a policy based on the number of countries participating and the possible sanctions for non-compliance.

Fit an additive model. Provide the summary output, the global null hypothesis, and p -value. Please describe the results and provide a conclusion.

Table 1:

	<i>Dependent variable:</i>
	choice
countries80 of 192	0.336*** (0.054)
countries160 of 192	0.648*** (0.054)
sanctions5%	0.192*** (0.062)
sanctions15%	-0.133** (0.062)
sanctions20%	-0.304*** (0.062)
Constant	-0.273*** (0.054)
Observations	8,500
Log Likelihood	-5,784.130
Akaike Inf. Crit.	11,580.260
<i>Note:</i>	*p<0.1; **p<0.05; ***p<0.01

After running the likelihood ratio test, we receive a p-value of 2.2e-16, which at a threshold of $\alpha = 0.05$, is an extremely significant result. This means that at least one of our predictors is a significant predictor in the logistic regression model.

Intercept When 20 of the 192 countries are participating and there are no sanctions the expected odds that an individual will support the policy is $\exp(-0.273) = 0.76$, which is our baseline odds ratio.

Intercept When 20 of the 192 countries are participating and there are no sanctions, the expected odds that an individual will support the policy are $\exp(-0.273) = 0.76$, which is our baseline odds ratio.

Countries 80 of 192 On average, having 80 out of 192 countries participating increases the log odds of supporting a policy by 0.336, holding all else constant.

Countries 160 of 192 On average, having 160 out of 192 countries participating increases the log odds of supporting a policy by 0.648, holding all else constant.

Sanctions 5% On average, having five percent sanctions increases the log odds of supporting a policy by 0.192, holding all else constant.

Sanctions 15% On average, having fifteen percent sanctions decreases the log odds of supporting a policy by 0.133, holding all else constant.

Sanctions 20% On average, having twenty percent sanctions decreases the log odds of supporting a policy by 0.304, holding all else constant.

```
1 m1 <- glm( #running an additive model
2   choice ~ countries + sanctions ,
3   data = climateSupport ,
4   family = "binomial" )
5
6 summary(m1) #summarizing
7 stargazer(m1)
8
9 m_null <- glm(choice ~ 1, data = climateSupport , family = binomial)
10 #running a null model
11 anova(m_null , m1, test = "LRT")
12 #running an ftest.
13
14 # Analysis of Deviance Table
15 #
16 # Model 1: choice ~ 1
17 # Model 2: choice ~ countries + sanctions
18 # Resid. Df Resid. Dev Df Deviance Pr(>Chi)
19 # 1      8499      11783
```

2. If any of the explanatory variables are statistically significant in this model, then:

- (a) For the policy in which nearly all countries participate [160 of 192], how does increasing sanctions from 5% to 15% change the odds that an individual will support the policy? (Interpretation of a coefficient)

Given that this is an additive model, country participation does not impact the change in odds when sanctions increase from 5 to 15%. Given this, we will mathematically compare the variable for 5% sanctions to 15% sanctions.

```
1 #2a
2 diff_s5_15 <- coef(m1)[ "sanctions15%" ] - coef(m1)[ "sanctions5%" ]
3 # -0.3251028
4 or <- exp( diff_s5_15 )
5 # 0.7224531
6 orpercent <- (or - 1) * 100
7 # -27.75469
```

When holding all other variables constant, an increase in sanctions from 5% to 15% decreases the log odds that an individual will support the policy by 0.325. In addition to the log odds, we can also calculate the odds ratio and express it as a percentage. We would then say that the odds of an individual supporting the policy would decrease by 27.27%

- (b) What is the estimated probability that an individual will support a policy if there are 80 of 192 countries participating with no sanctions?

As stated above, in an additive model, the number of participating countries does not affect the change in policy support when moving from 5 to 15% sanctions. Therefore, as stated above, when sanctions are increased from 5% to 15%, and all other variables are held constant, the log odds that an individual will support the policy decrease by 0.325, or, expressed as by the odds ratio, a decrease of 27.75%.

What is the estimated probability that an individual will support a policy if there are 80 of 192 countries participating with no sanctions?

The estimated probability that an individual would support a policy if 80 out of 192 countries participate with no sanctions is 0.5159 or 51.59%

```
1 #2c
2 #computing for 80/192 country participation and 0 sanctions
3 odds_80 <- coef(m1)[ "(Intercept)" ] + coef(m1)[ "countries80 of 192" ]
4 #calculating the probability
5 probability_80 <- exp(odds_80) / (1 + exp(odds_80))
6 #checking the result.
7 probability_80
8 # 0.5159191
```

3. Would the answers to 2a and 2b potentially change if we included an interaction term in this model? Why?

- Perform a test to see if including an interaction is appropriate.

Our interpretation of 2a and 2b would change if we added an interaction term. This is because, with the additive model, when looking at the change in support between 5% and 15% sanctions, varying levels of country participation would not affect the difference, as we hold the other variables constant. If we had an interaction term in the model, the difference between 5% and 15% sanctions would not be constant and would vary alongside levels of country participation.

```

1 m_interaction <- glm(choice ~ countries * sanctions ,
2                       family = binomial , data = climateSupport)
3
4 summary(m_interaction)
5 stargazer(m_interaction)
6 #creating a model with an interactive term
7 anova(m1, m_interaction , test = "LRT")
8
9 # Analysis of Deviance Table
10 # Model 1: choice ~ countries + sanctions
11 # Model 2: choice ~ countries * sanctions
12 # Resid. Df Resid. Dev Df Deviance Pr(>Chi)
13 # 1      8494      11568
14 # 2      8488      11562  6    6.2928  0.3912

```

After running the test with the additive and interactive models, we obtain a p-value of 0.39. At a threshold of $\alpha = 0.05$, this is not a significant result, meaning that the parallel lines with the additive model would suffice.
